INTRODUCTION

The vascular system is essential for providing oxygen and nutrients, removing metabolic waste products, and furnishing efficient access of leukocytes to tissues throughout larger animals. Angiogenesis, the sprouting of new capillaries, is required for the development of the vascular system and, consequently, the growth of vertebrates.\(^1\)

Vascular endothelial growth factor (VEGF) is a pivotal regulator of angiogenesis and is suggested to play an important role in tumor growth and dissemination.\(^2,3\) Besides being a tumor growth-promoting factor, VEGF is also characterized as an inflammatory molecule.\(^4\) It is synthesized by a variety of inflammatory cells including endothelial cells, megakaryocytes,\(^5\) granulocytes,\(^6\) activated lymphocytes,\(^7\) and macrophages\(^8\) and may be released from these cells following activation.\(^9\) Thereby VEGF may contribute to local hyperpermeability of traumatized or inflamed tissue as well as induce revascularization of the inflamed area.

ABSTRACT

Objective: Anesthesia and surgical intervention, leads to the development of systemic inflammatory response. The severity of the inflammatory response depends on the pharmacological effects of anesthetic agents and duration of anesthesia. Objective of the study was to investigate the effect of nitrous oxide on VEGF and VEGFR1 levels in patients undergoing surgery.

Methods: Forty-four patients undergoing elective urological surgery were included in the study. Anesthesia maintenance was provided with 1-2 MAC sevoflurane, O\(_2\) 50%, N\(_2\)O 50% in 4L/m transporter gas for group 1 (n=22) and 1-2 MAC sevoflurane, O\(_2\) 50%, air 50% in 4L/m transporter gas for group 2 (n=22) Venous blood samples for the measurement of VEGF and VEGFR1 were taken before the induction of anesthesia, 60 minutes of anesthesia induction, at the end of anesthesia and 24 hours after operation. In statistical analysis Bonferroni test and analysis of variance at the repeated measures were used

Results: In the postoperative period serum VEGF levels had decreased significantly in both group whereas VEGFR1 did not show a significant change.

Conclusions: Nitrous oxide showed significant effect on angiogenic parameters. Further detailed studies are required to evaluate the effect of nitrous oxide.

Several receptors for VEGF have been identified. Of these the soluble form of VEGFR1 (sVEGFR1) is presumed to antagonize the effects of VEGF by a direct competitive binding of VEGF.

Nitrous oxide (N₂O; laughing gas) has been widely used in clinical practice for decades because its effective analgesic properties are achieved at concentrations below those required for general anesthesia. Nevertheless, several adverse effects, including megaloblastic anemia, homocysteinemia and its possible risk for atherosclerosis, thrombosis, cognitive dysfunction, neurotoxicity, possible teratogenicity, increased intracranial pressure and cerebral blood flow, expansion of air spaces and hypoxia, post-operative nausea and vomiting, and possible immunosuppression are known.

Surgical trauma is followed by inflammatory and wound healing processes, with local release of various growth factors including VEGF. In animal models, surgery, trauma and inflammation have been shown to facilitate angiogenesis, tumour growth and metastasis, the effect being both local and systemic.

The stress response to surgery is a major neuroendocrine and cytokine response to surgical trauma, characterized by increases in catecholamine and steroid hormones, with predictable metabolic consequences, including hyperglycemia and negative nitrogen balance. It is possible that cytokines increased by the surgical stress response may be linked with some of the angiogenic factors associated with elective urological surgery.

The aim of the present study was to investigate the influence of nitrous oxide on VEGF and VEGFR1 in order to detect any effect that this agent might have on an inflammatory response.

**METHODS**

This study was approved by Ethical Committee at Karaelmas University Application and Research Hospital CM, dated January 15th, 2009. Forty four Society of Anesthesia (ASA) risk scores I-III adult patients who were between 18 and 65 years and were to undergo an elective urological surgical initiative that would last 1 to 4 hours in the main operation room at Karaelmas University Application and Research Hospital were included. The study was conducted between January 2009 and January 2010. Patients with chronic metabolic diseases, liver failures and acute anemia were not included.

All the patients were applied the standard IM midazolam (0.07 mg/kg) premedication one hour before the surgery. Blood samples were taken from the patients prior to anesthesia in order to determine their VEGF, VEGFR1 levels. Before induction, all the patients were applied 5-7 ml/kg Ringer Laktat fluid replacement. All patients were preoxygenated with 10 L/dk 100% of oxygen for one minute. Anesthetic induction was done with 2.4 mg/kg of propofol and 1 µg/kg of fentanyl. Intubation was done three minutes after 0.6 mg/kg of rocuronium was given as a muscle relaxant agent. Following the intubation, a high current of 6 L/dk was applied for 5 minutes.

Maintenance of anesthesia was done with 1-2 MAC sevoflurane in group 1 (n=22), keeping O₂ at 50% and N₂O at 50% and with 1-2 MAC sevoflurane in group 2 (n=22) under 4 L/dk carrier gas, keeping O₂ at 50% and air at 50%. Maintenance analgesia need was met in group 2 with 1 mcg/kg/saat fentanyl infusion. Ventilation tidal volume (TV) was kept at 6-8 ml/kg, I:E ratio at 1:2 and respiratory frequency was maintained in a way to keep ETCO₂ at 35-40 mmHg, which makes normocapnia possible. FiO₂ value was preserved between 30 and 35%. Anesthetics were stopped and patient was ventilated with 100% of O₂ when the last skin suture was begun before the operation ended. Muscle relaxant was antagonised with 0.05 mg / kg of neostigmin and 0.01 mg/kg of atropine. The patient was respirated by hand after the antagonists were applied and spontaneous respiration was controlled every ten seconds In order to determine the levels of VEGF and VEGFR1, blood samples were taken. from patients

After vascular access was obtained, blood samples were taken from all the patients before anesthesia (Pre-operative 0th min), at the 60th min of anesthesia (Intra-operative 60th min), after anesthetic agents were stopped (Post-operative 0th min) and at Post-operative 24 th hr. After the blood samples were congealed, they were centrifuged at 3500 rpm for five minutes. The serums separated after centrifuges were kept to be analysed at - 80°C.

**VEGF measurement:** VEGF levels were assayed by an enzyme-linked immunosorbert assay (ELISA) kit (Catalog No: KHG0112: 1 plate, Camarillo, USA). Detection limit of the assay is <5 pg/ml.

**VEGFR1 measurement:** VEGFR1 levels were assayed by an enzyme-linked immunosorbest assay (ELISA) kit (Catalog No: BMS268/2: 1 plate, Vienna, Austria). Detection limit of the assay is 6 ng/ml.

**Statistical analysis:** Statistical evaluation was done using the SPSS 18.0 program. Descriptive statistics were expressed as mean ± standard deviation for...
numeric data and as number and percentage for categorical data. Compatibility of the measured variables with normal distribution was examined with the Kolmogorov-Smirnov test. Significance test of the difference between two means was used for the differences of measured variables between the groups. Differences of categorical variables between the groups were evaluated with chi-square test. Changes in measured variables in time for the repetitive measurements were examined with single direction variance analysis.

Paired comparisons were done with Bonferroni test when analysis yielded any differences. Results were evaluated in 95% confidence interval and statistical significance was taken as p<0.05.

RESULTS

The measurement values of VEGF and VEGFR1 belonging to the group of nitrous oxide-administered patients at preop, intraop 60th minute, postop 0th minute and postop 24th hours are given in Table-I.

The change in VEGF depending on time in the nitrous oxide-administered patient group was found to be significant (p<0.001). VEGF levels in preop. 0th min is statistically higher than other times. There was no significant difference between the levels of VEGF at other times.

No significant difference between times in terms of VEGFR1 was found in the group of patients who receive nitrous oxide (p=0.159).

Svendsen et al (2005) investigated that the effect of major and minor surgery on variations in sVEGF and sVEGFR1 concentrations in vivo and on bacterial antigen induced release of sVEGF and sVEGFR1 from whole blood in vitro. They suggested that plasma sVEGF and sVEGFR1 concentrations did not change during surgery and in vitro bacterial stimulation led to increased release of sVEGF, which was not compensated for by an equivalent increase in sVEGFR1.

DISCUSSION

Angiogenesis, or the formation of new blood vessels from pre-existing ones plays a pivotal role during embrional development and later, in adult life, in a variety of physiological and pathological conditions, such as malignancy and chronic inflammation. Diseased or injured cells in response to genetic alterations, hypoxia, hypoglycemia, mechanical stress, and/or inflammatory proteins, release pro-angiogenic growth factors such as vascular endothelial growth factor (VEGF) into the surrounding tissue. VEGF is the major endogenous regulator of endothelial cell proliferation, migration, and differentiation.

Svendsen et al (2005) also evaluated perioperative plasma concentrations of soluble VEGF (sVEGF) and soluble VEGFR1 (sVEGFR1) in patients undergoing elective colectomy. They found that the major surgical trauma led to significant intra- and postoperative changes in sVEGF and sVEGFR1. The high preoperative levels were significantly decreased 30 days after surgery. The intra- and postoperative changes of both molecule levels were similar in patients undergoing laparoscopically assisted and open colectomy.  

An insignificant decrease was observed on the post-operative day one in the study in which Futami R et al investigated serum VEGF levels following a major surgical damage. However, there was an increase in the serum VEGF levels after the day one. It was reported that this increase peaked on the postop day 14. Researchers suggested that the postoperative VEGF increase might be the angiogenic response to tissue repair. Compared with preop levels, VEGF levels were found to be low at postop 4 and 24 hours in the 30 patients who had mastectomy operation under general anesthesia using nitrous oxide but no statistically significant difference was found. A significant decrease was seen in VEGF levels in patients with oesophagus cancer on day one following surgical trauma. VEGF levels started to increase on day three and receded to preop levels on day five. 

VEGF and soluble VEGFR1 levels were examined in a study in which 61 patients of abdominal surgery who were given general anaesthesia without giving nitrous oxide suggests that the decrease occurred due to nitrous oxide. The fact that there was not a significant change in serum soluble VEGFR1 levels in both groups shows that soluble VEGFR1 did not contribute to the decrease in VEGF levels. These results suggest that the decrease in VEGF levels were due to dilutional effect arising from stress response.
